

CS11-747 Neural Networks for NLP

Parsing with Dynamic Programming

Graham Neubig

Carnegie Mellon University

Language Technologies Institute

Site

<https://phontron.com/class/nn4nlp2019/>

Two Types of Linguistic Structure

- **Dependency:** focus on relations between words

- **Phrase structure:** focus on the structure of the sentence

Parsing

- Predicting linguistic structure from input sentence
- **Transition-based models**
 - step through actions one-by-one until we have output
 - like history-based model for POS tagging
- **Dynamic programming-based models**
 - calculate probability of each edge/constituent, and perform some sort of dynamic programming
 - like linear CRF model for POS

Minimum Spanning Tree Parsing Models

(First Order) Graph-based Dependency Parsing

- Express sentence as fully connected directed graph
- Score each edge independently
- Find maximal spanning tree

Graph-based vs. Transition Based

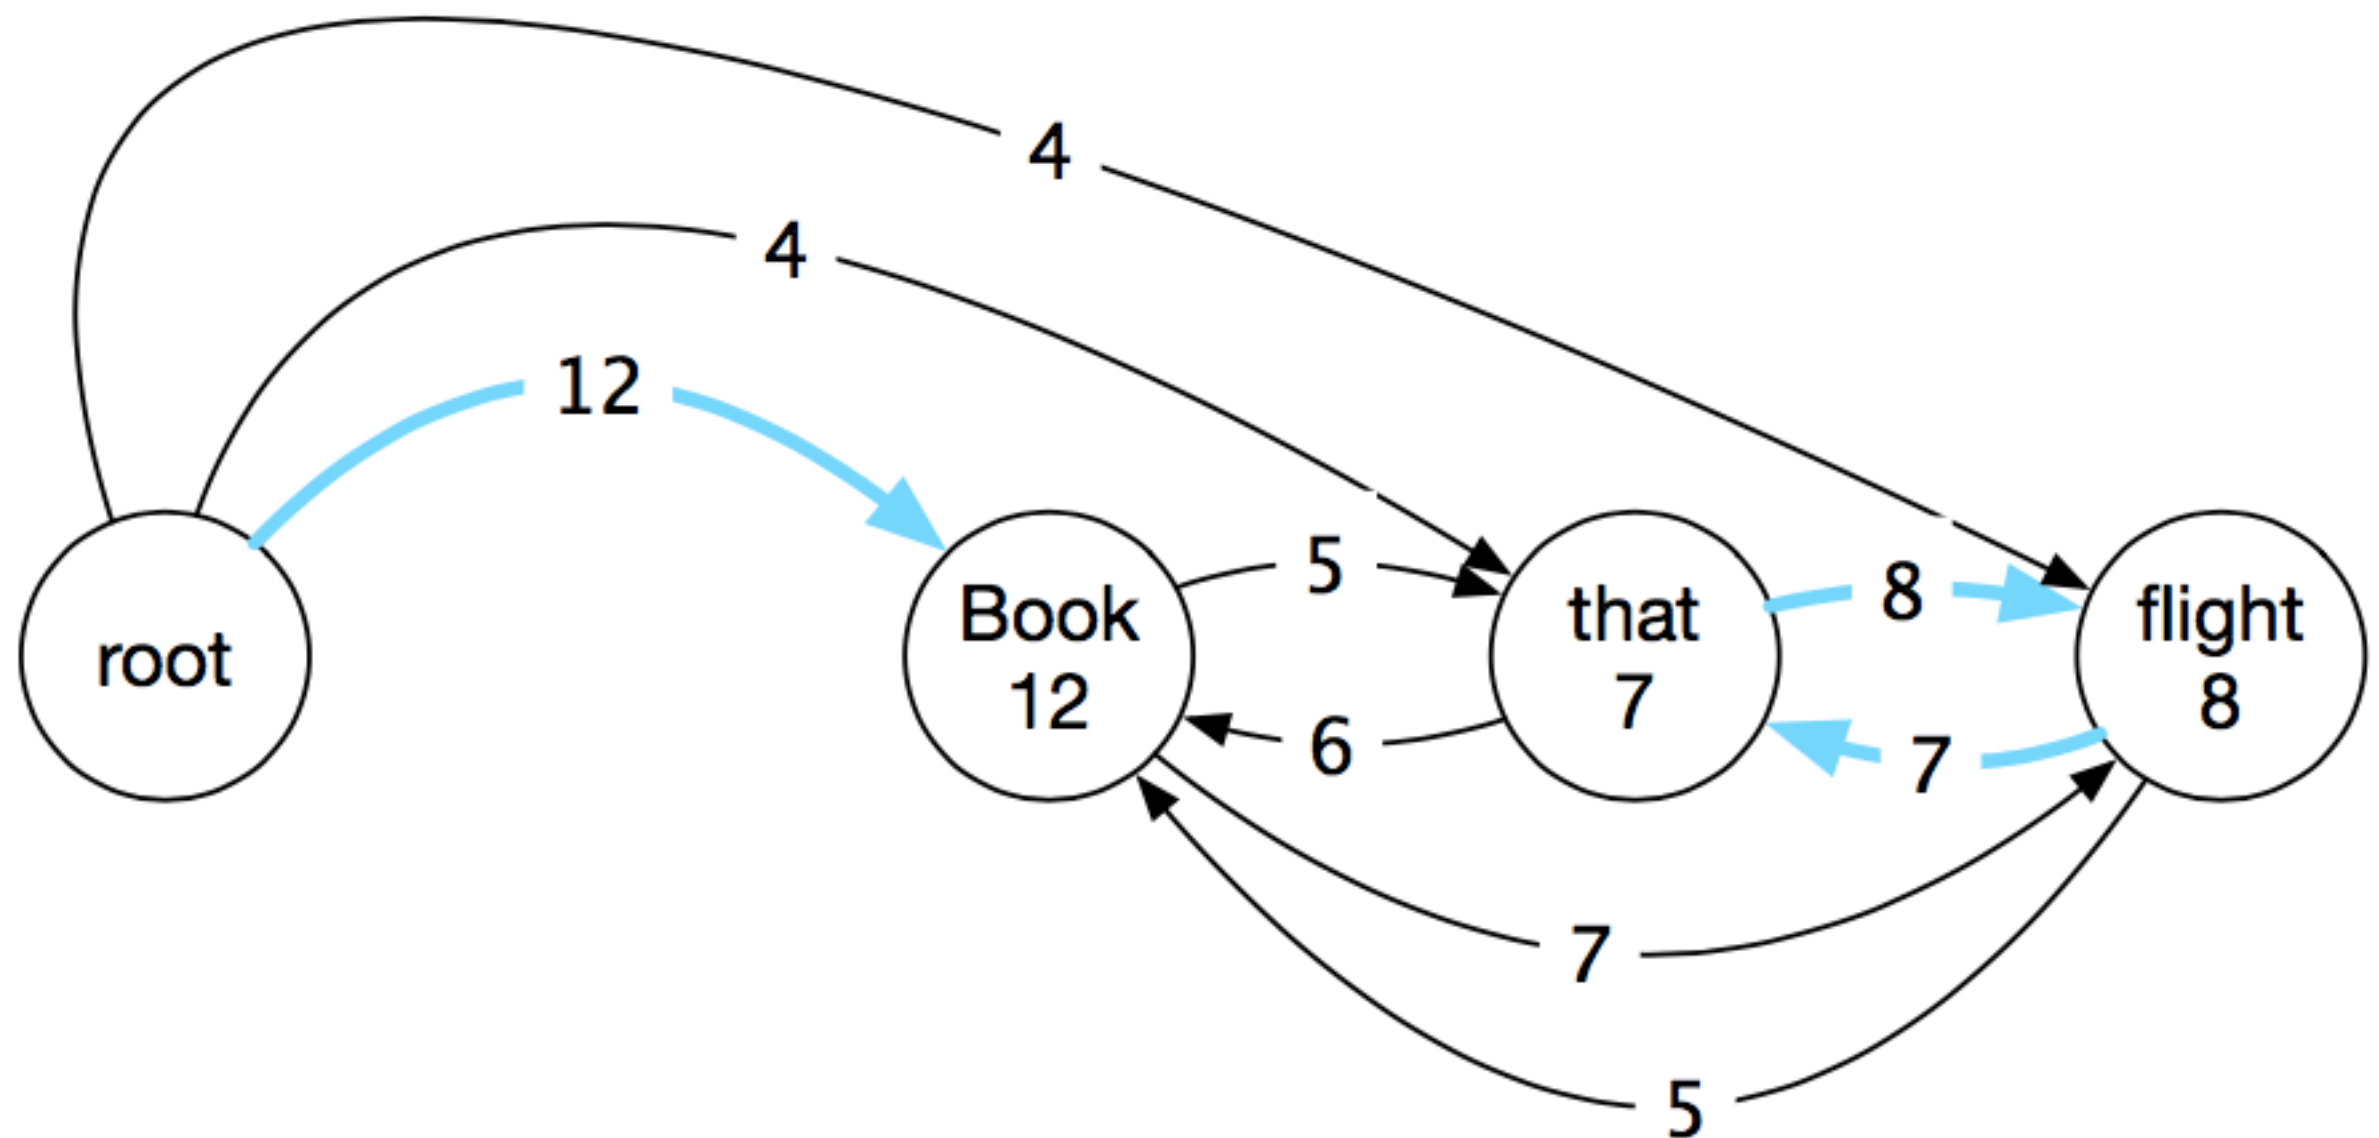

- **Transition-based**
 - + Easily condition on infinite tree context (structured prediction)
 - - Greedy search algorithm causes short-term mistakes
- **Graph-based**
 - + Can find exact best global solution via DP algorithm
 - - Have to make local independence assumptions

Chu-Liu-Edmonds

(Chu and Liu 1965, Edmonds 1967)

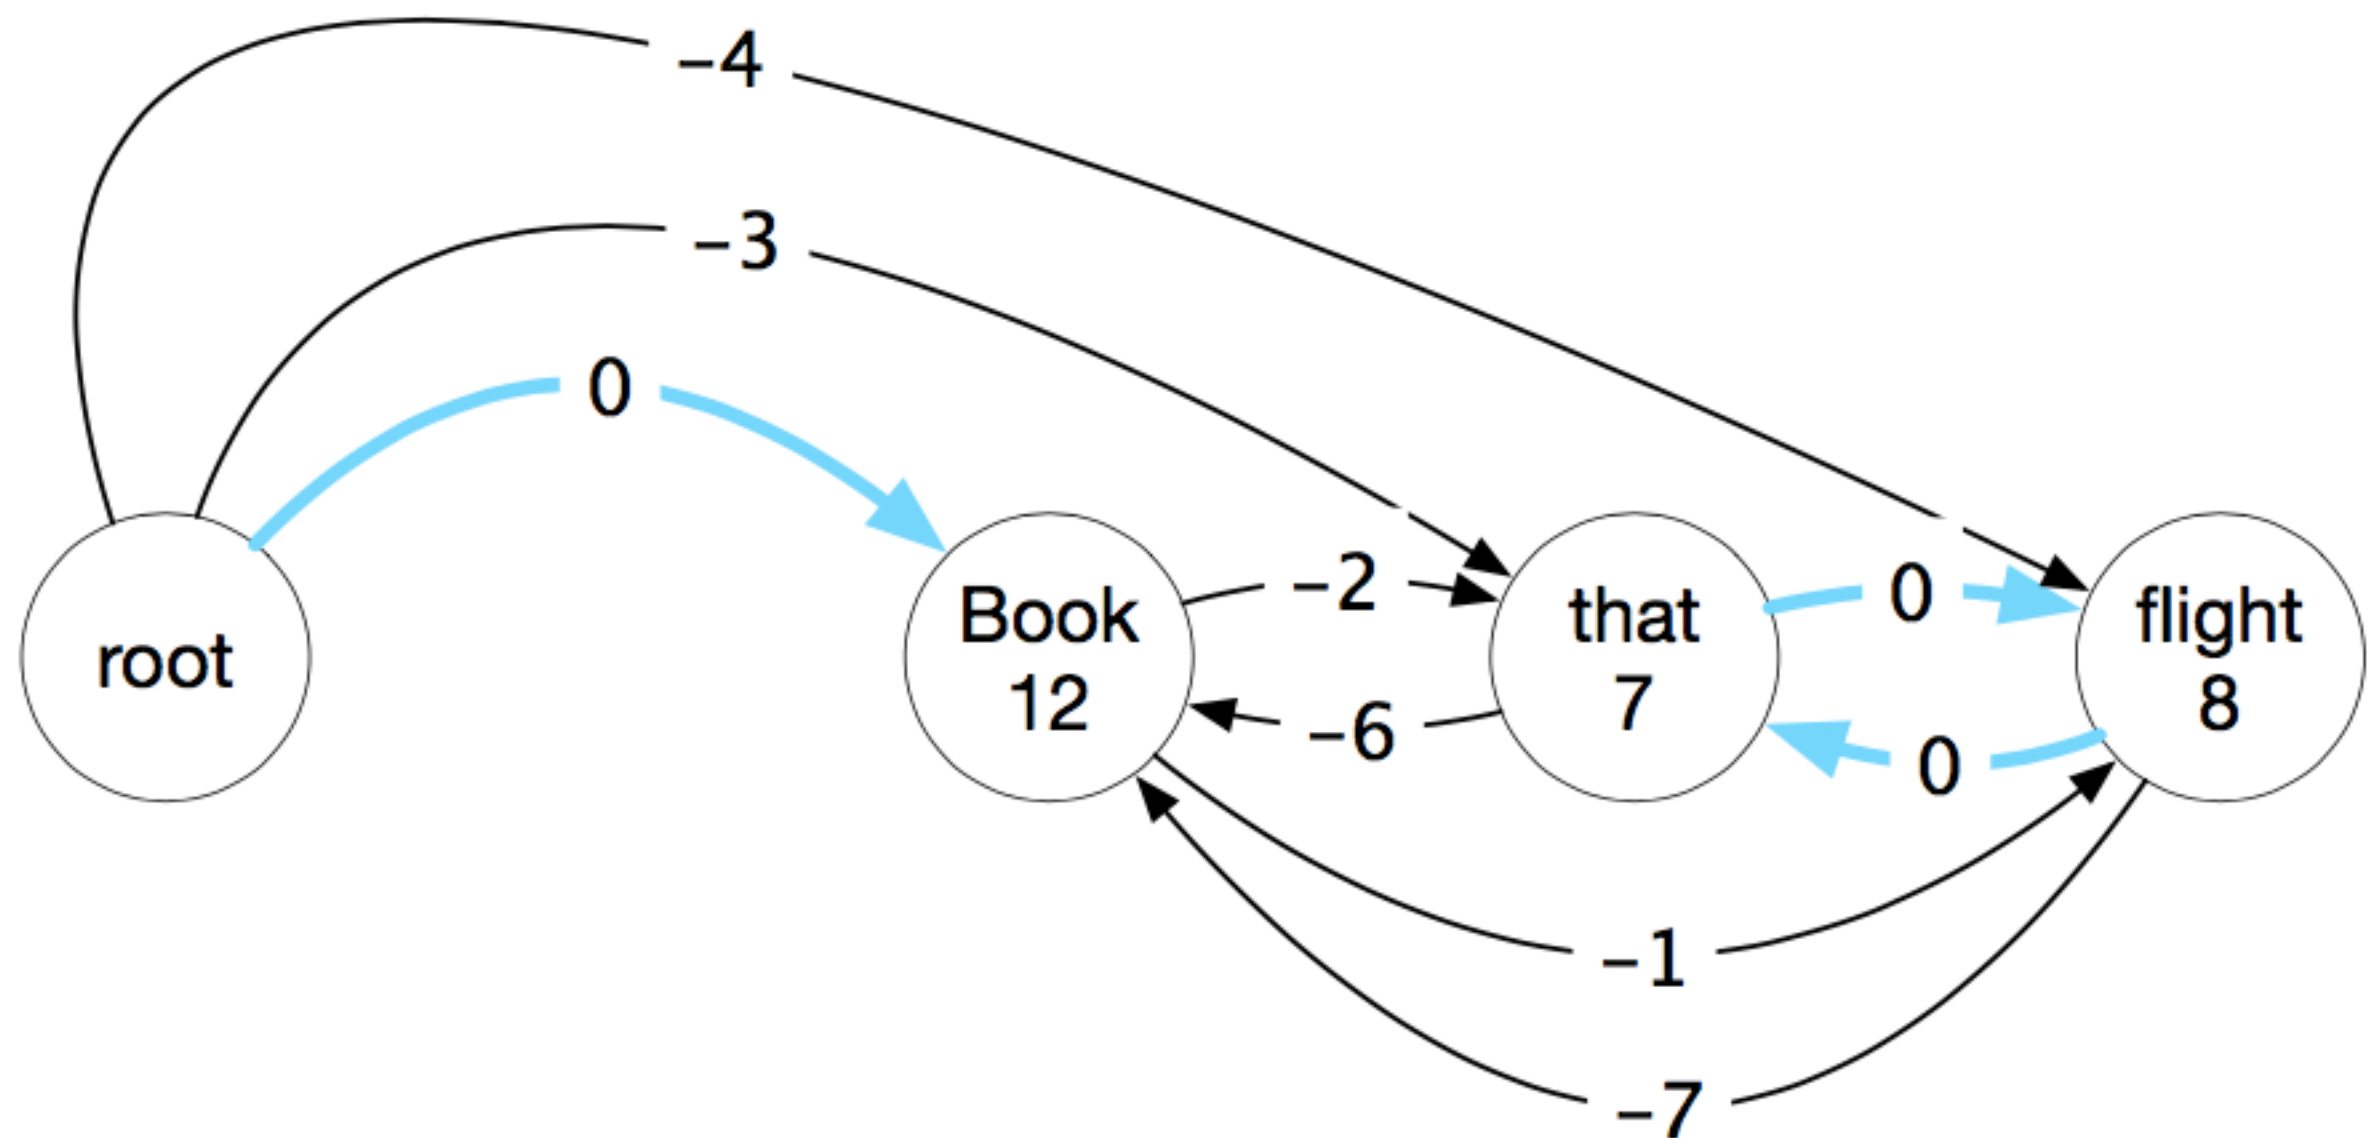

- We have a graph and want to find its spanning tree
- **Greedily select** the best incoming edge to each node (and subtract its score from all incoming edges)
- If there are cycles, select a cycle and **contract** it into a single node
- **Recursively call** the algorithm on the graph with the contracted node
- **Expand** the contracted node, deleting an edge appropriately

Chu-Liu-Edmonds (1): Find the Best Incoming

(Figure Credit: Jurafsky and Martin)

Chu-Liu-Edmonds (2): Subtract the Max for Each

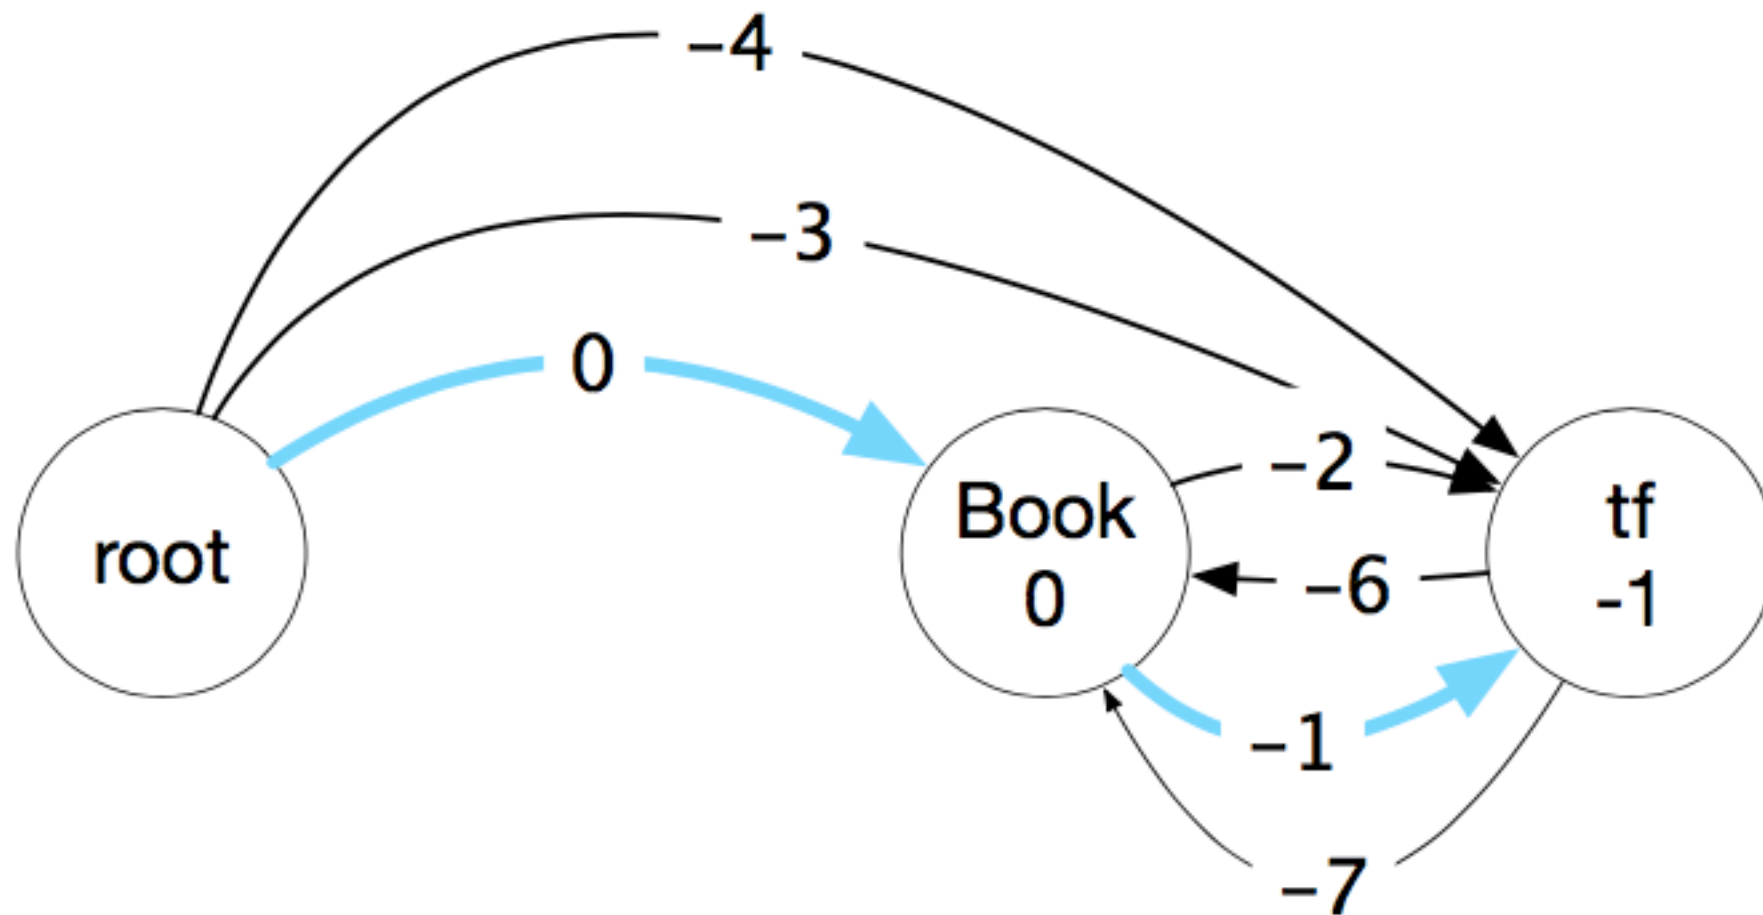

(Figure Credit: Jurafsky and Martin)

Chu-Liu-Edmonds (3): Contract a Node

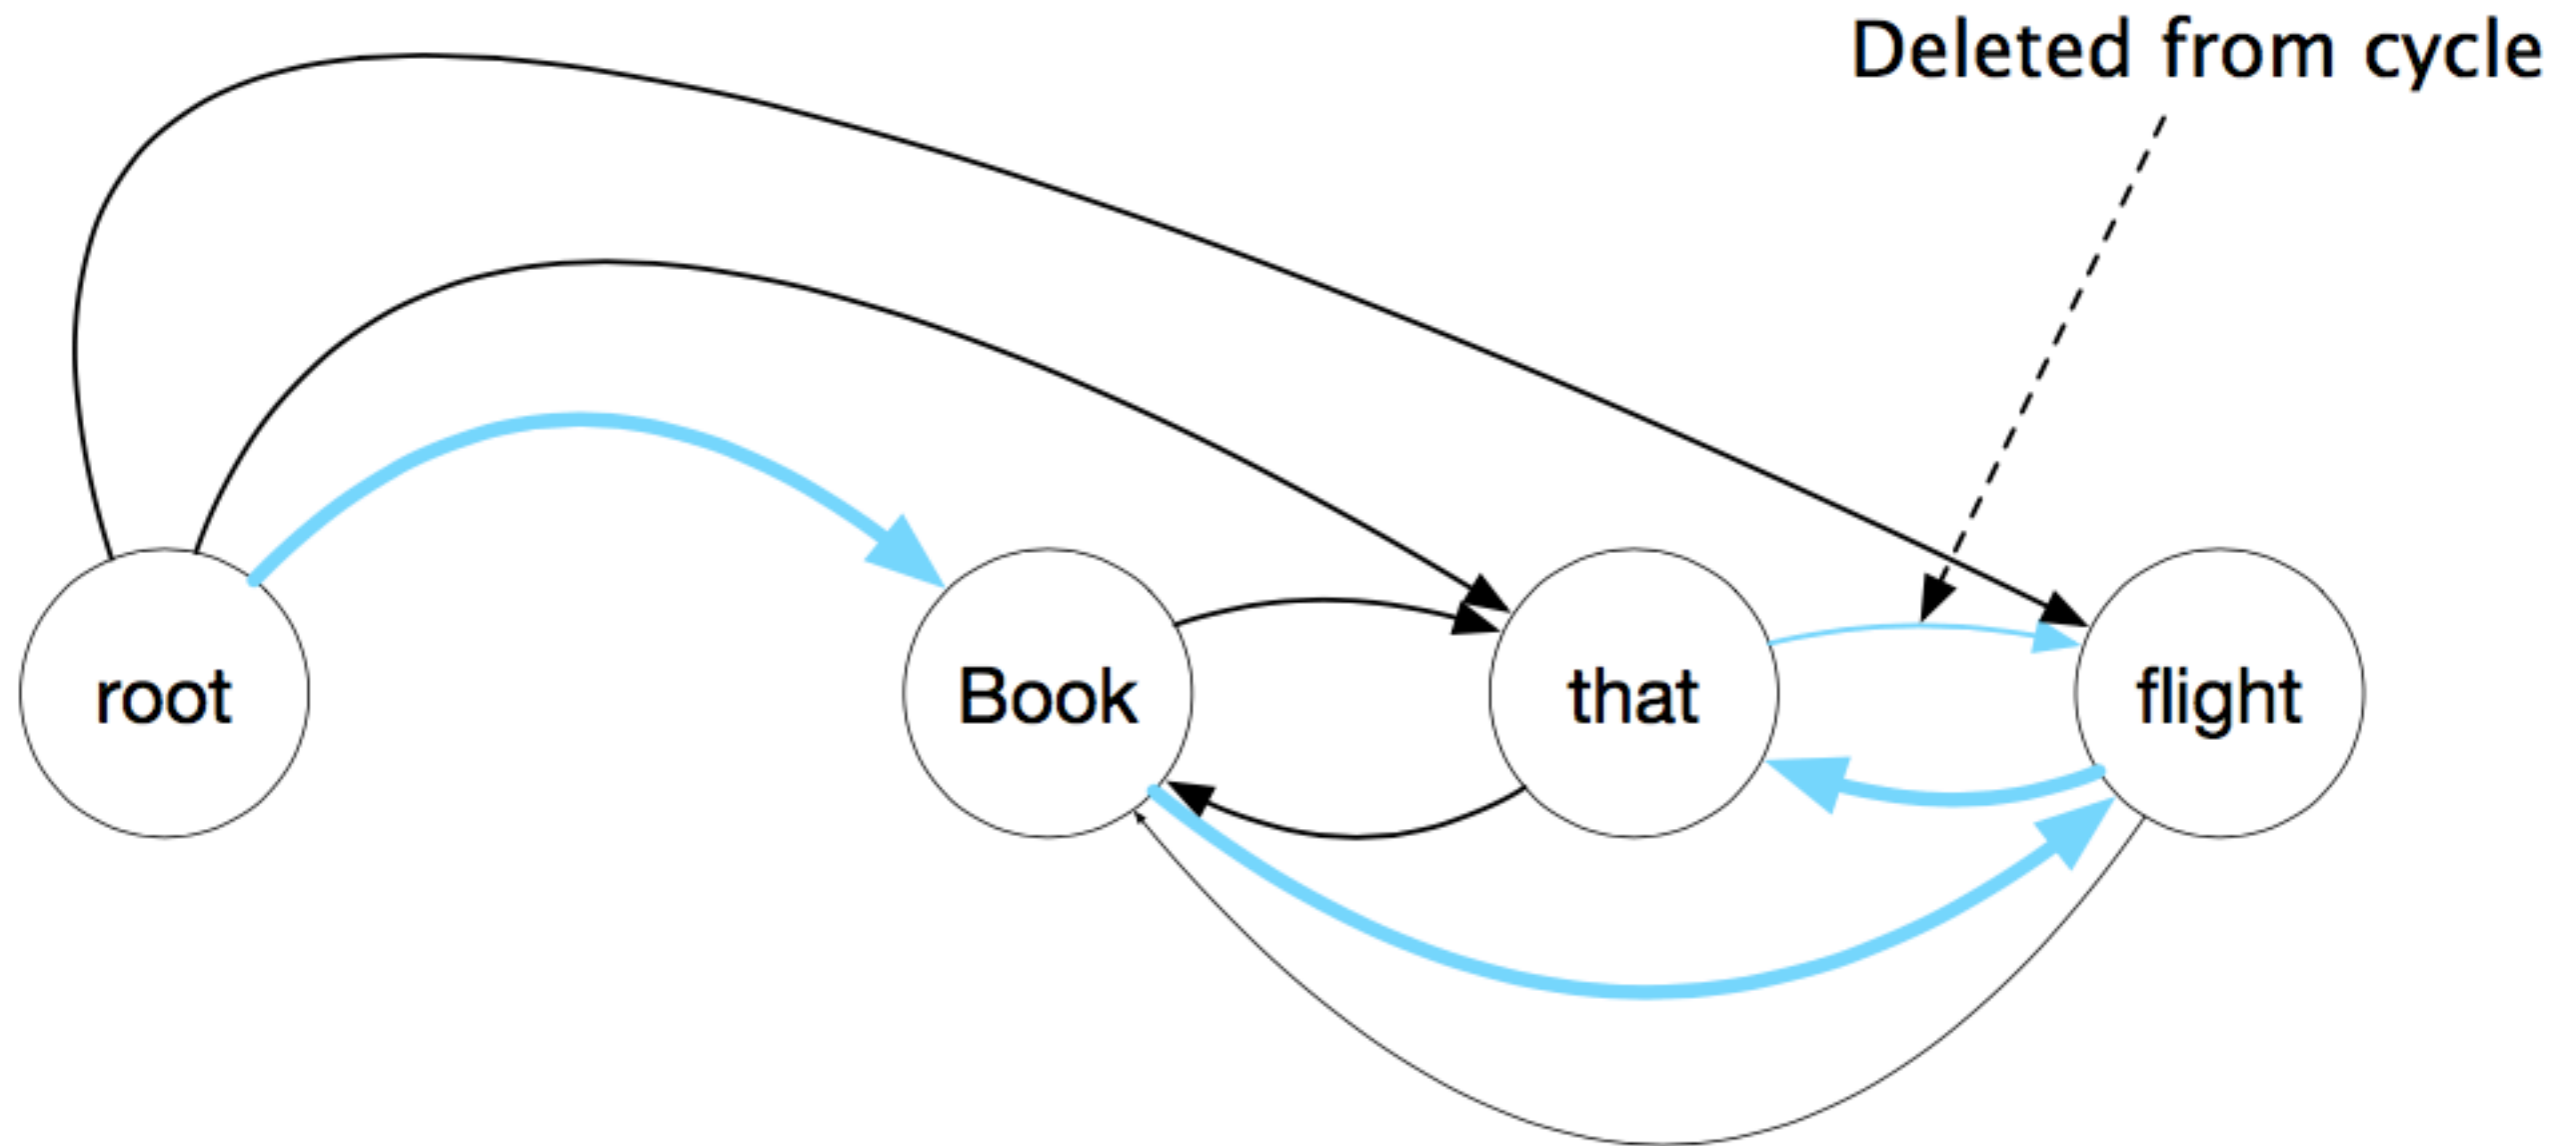

(Figure Credit: Jurafsky and Martin)

Chu-Liu-Edmonds (4): Recursively Call Algorithm

(Figure Credit: Jurafsky and Martin)

Chu-Liu-Edmonds (5): Expand Nodes and Delete Edge

(Figure Credit: Jurafsky and Martin)

Other Dynamic Programs

- **Eisner's Algorithm** (Eisner 1996):
 - A dynamic programming algorithm to combine together trees in $O(n^3)$
 - Creates *projective* dependency trees (Chu-Liu-Edmonds is *non-projective*)
- **Tarjan's Algorithm** (Tarjan 1979, Gabow and Tarjan 1983):
 - Like Chu-Liu-Edmonds, but better asymptotic runtime $O(m + n \log n)$

Training Algorithm

(McDonald et al. 2005)

- Basically use **structured hinge loss** (covered in structured prediction class)
- Find the highest scoring tree, penalizing each correct edge by the margin
- If the found tree is not equal to the correct tree, update parameters using hinge loss

Features for Graph-based Parsing (McDonald et al. 2005)

- What features did we use before neural nets?

b)

c)

a)

Basic Uni-gram Features
p-word, p-pos
p-word
p-pos
c-word, c-pos
c-word
c-pos

Basic Big-ram Features
p-word, p-pos, c-word, c-pos
p-pos, c-word, c-pos
p-word, c-word, c-pos
p-word, p-pos, c-pos
p-word, p-pos, c-word
p-word, c-word
p-pos, c-pos

In Between POS Features
p-pos, b-pos, c-pos
Surrounding Word POS Features
p-pos, p-pos+1, c-pos-1, c-pos
p-pos-1, p-pos, c-pos-1, c-pos
p-pos, p-pos+1, c-pos, c-pos+1
p-pos-1, p-pos, c-pos, c-pos+1

Table 1: Features used by system. p-word: word of parent node in dependency tree. c-word: word of child node. p-pos: POS of parent node. c-pos: POS of child node. p-pos+1: POS to the right of parent in sentence. p-pos-1: POS to the left of parent. c-pos+1: POS to the right of child. c-pos-1: POS to the left of child. b-pos: POS of a word in between parent and child nodes.

- All conjoined with arc direction and arc distance
- Also use POS combination features
- Also represent words w/ prefix if they are long

Higher-order Dependency Parsing

(e.g. Zhang and McDonald 2012)

- Consider multiple edges at a time when calculating scores

First Order

Second Order

Third Order

- + Can extract more expressive features
- - Higher computational complexity, approximate search necessary

Neural Models for Graph-based Parsing

Neural Feature Combinators

(Pei et al. 2015)

- Extract traditional features, let NN do feature combination
 - Similar to Chen and Manning (2014)'s transition-based model
- Use **cube + tanh** activation function
- Use **averaged embeddings of phrases**
- Use **second-order features**

Phrase Embeddings

(Pei et al. 2015)

- Motivation: words surrounding or between head and dependent are important clues
- Take average of embeddings

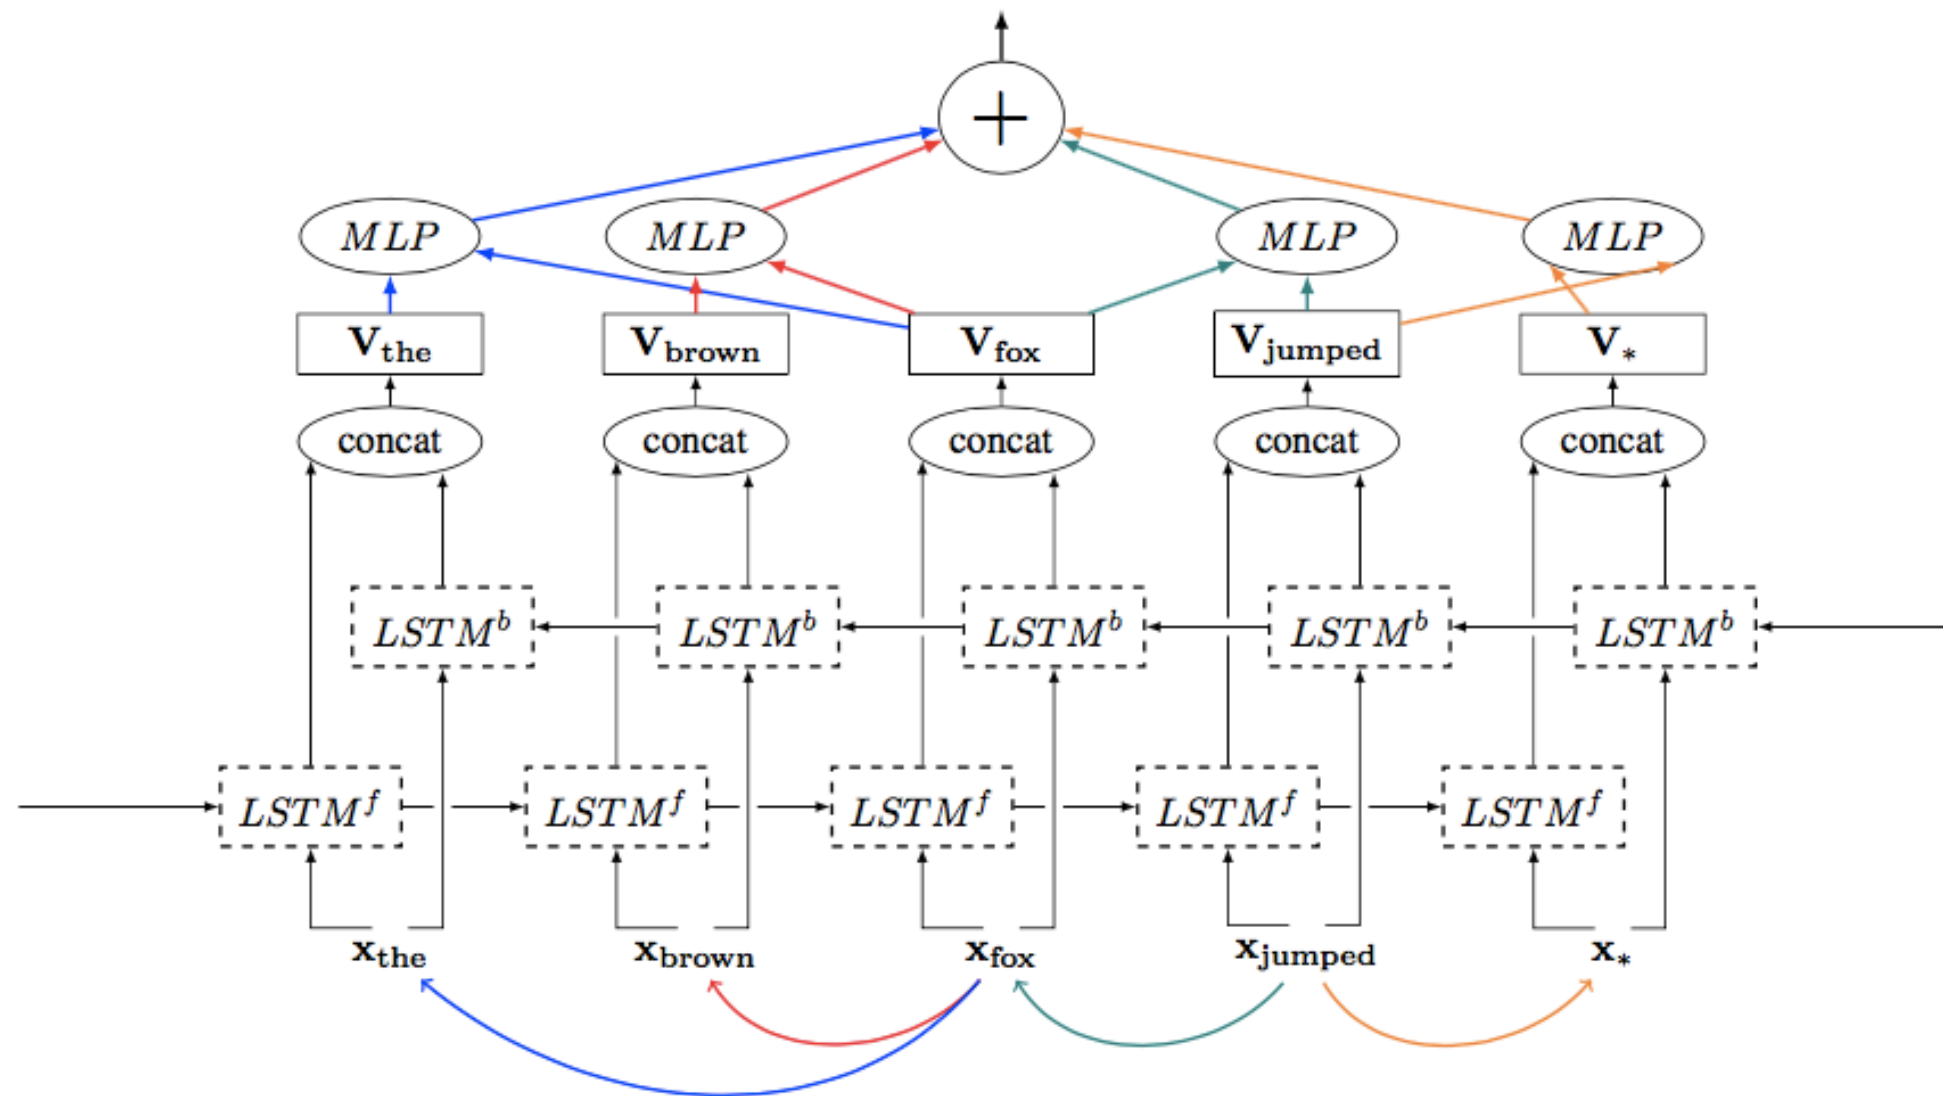

Do Neural Feature Combinators Help?

(Pei et al. 2015)

- Yes!
 - 1st-order: LAS 90.39->91.37, speed 26 sent/sec
 - 2nd-order: LAS 91.06->92.13, speed 10 sent/sec
- 2nd-order neural better than 3rd-order non-neural at UAS

BiLSTM Feature Extractors

(Kipperwasser and Goldberg 2016)

- Simpler and better accuracy than manual extraction

BiAffine Classifier

(Dozat and Manning 2017)

$$\begin{aligned}\mathbf{h}_i^{(arc-dep)} &= \text{MLP}^{(arc-dep)}(\mathbf{r}_i) \\ \mathbf{h}_j^{(arc-head)} &= \text{MLP}^{(arc-head)}(\mathbf{r}_j) \\ \mathbf{s}_i^{(arc)} &= H^{(arc-head)} U^{(1)} \mathbf{h}_i^{(arc-dep)} \\ &\quad + H^{(arc-head)} \mathbf{u}^{(2)}\end{aligned}$$

Learn specific representations
for head/dependent for each word

Calculate score of each arc

- Just optimize the likelihood of the parent, no structured training
 - This is a local model, with global decoding using MST at the end
- Best results (with careful parameter tuning) on universal dependencies parsing task

Global Training

- Previously: margin-based global training, local probabilistic training
- What about global probabilistic models?

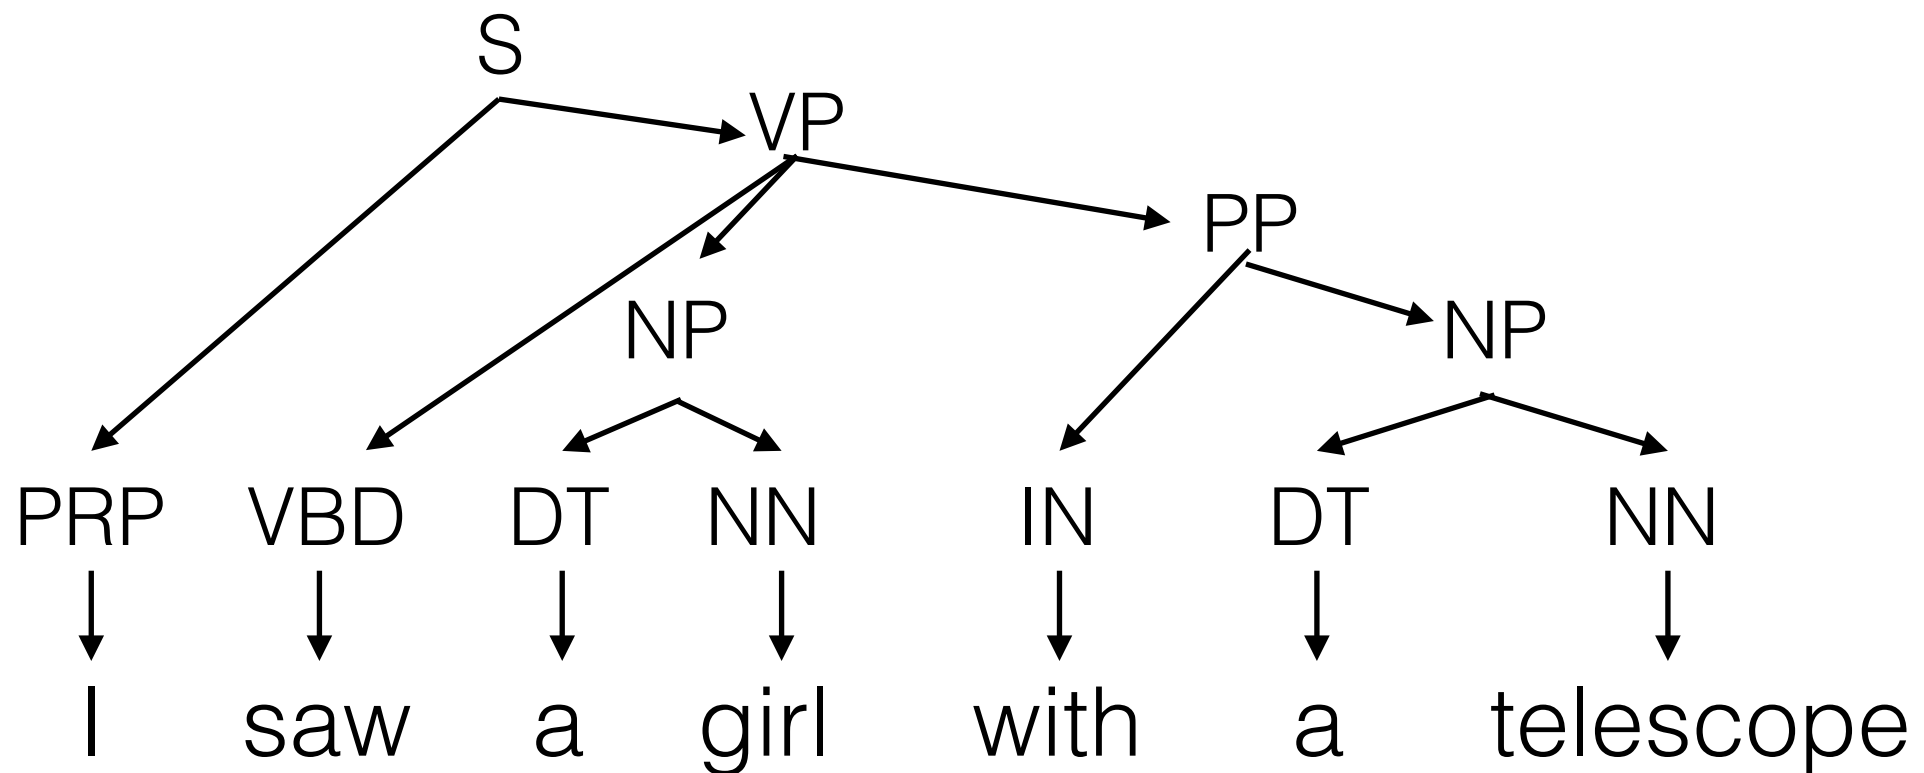

$$P(Y \mid X) = \frac{e^{\sum_{j=1}^{|Y|} S(y_j \mid X, y_1, \dots, y_{j-1})}}{\sum_{\tilde{Y} \in V^*} e^{\sum_{j=1}^{|\tilde{Y}|} S(\tilde{y}_j \mid X, \tilde{y}_1, \dots, \tilde{y}_{j-1})}}$$

- Algorithms for calculating partition functions:
 - **Projective parsing:** Eisner algorithm is a bottom-up CKY-style algorithm for dependencies (Eisner et al. 1996)
 - **Non-projective parsing:** Matrix-tree theorem can compute marginals over directed graphs (Koo et al. 2007)
- Applied to neural models in Ma et al. (2017)

Dynamic Programming for Phrase Structure Parsing

Phrase Structure Parsing

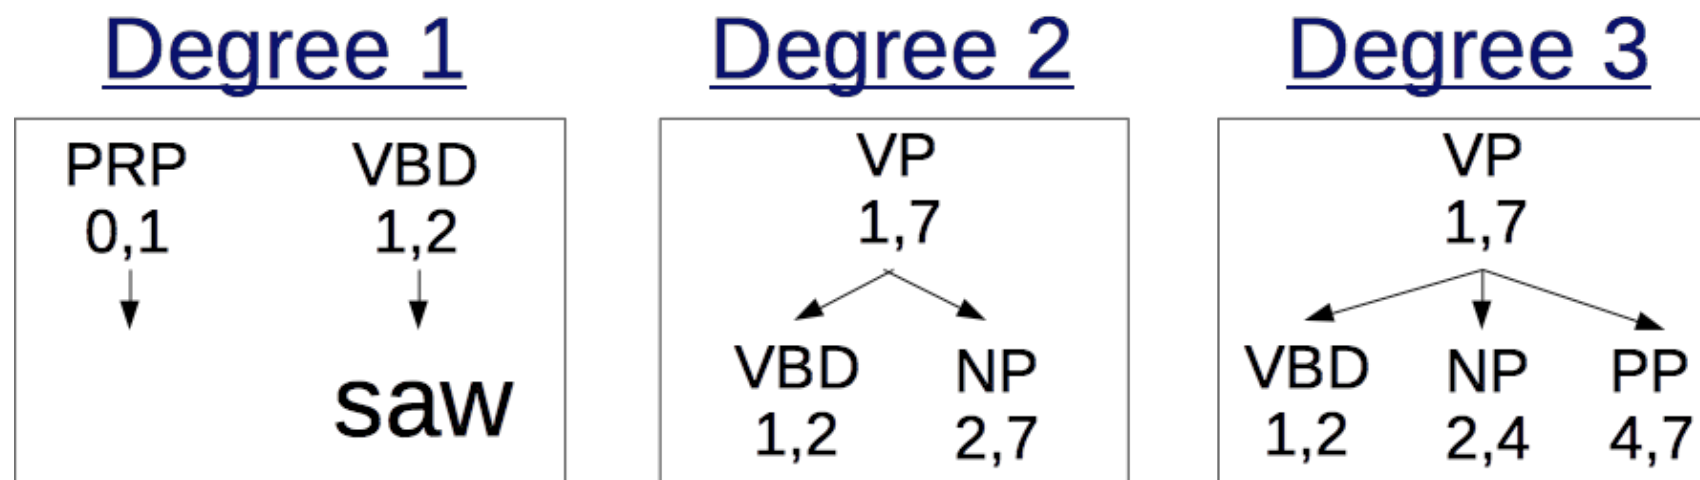

- Models to calculate phrase structure

- Important insight: parsing is similar to tagging
 - Tagging is search in a **graph** for the best **path**
 - Parsing is search in a **hyper-graph** for the best **tree**

What is a Hyper-Graph?

- The “degree” of an edge is the number of children

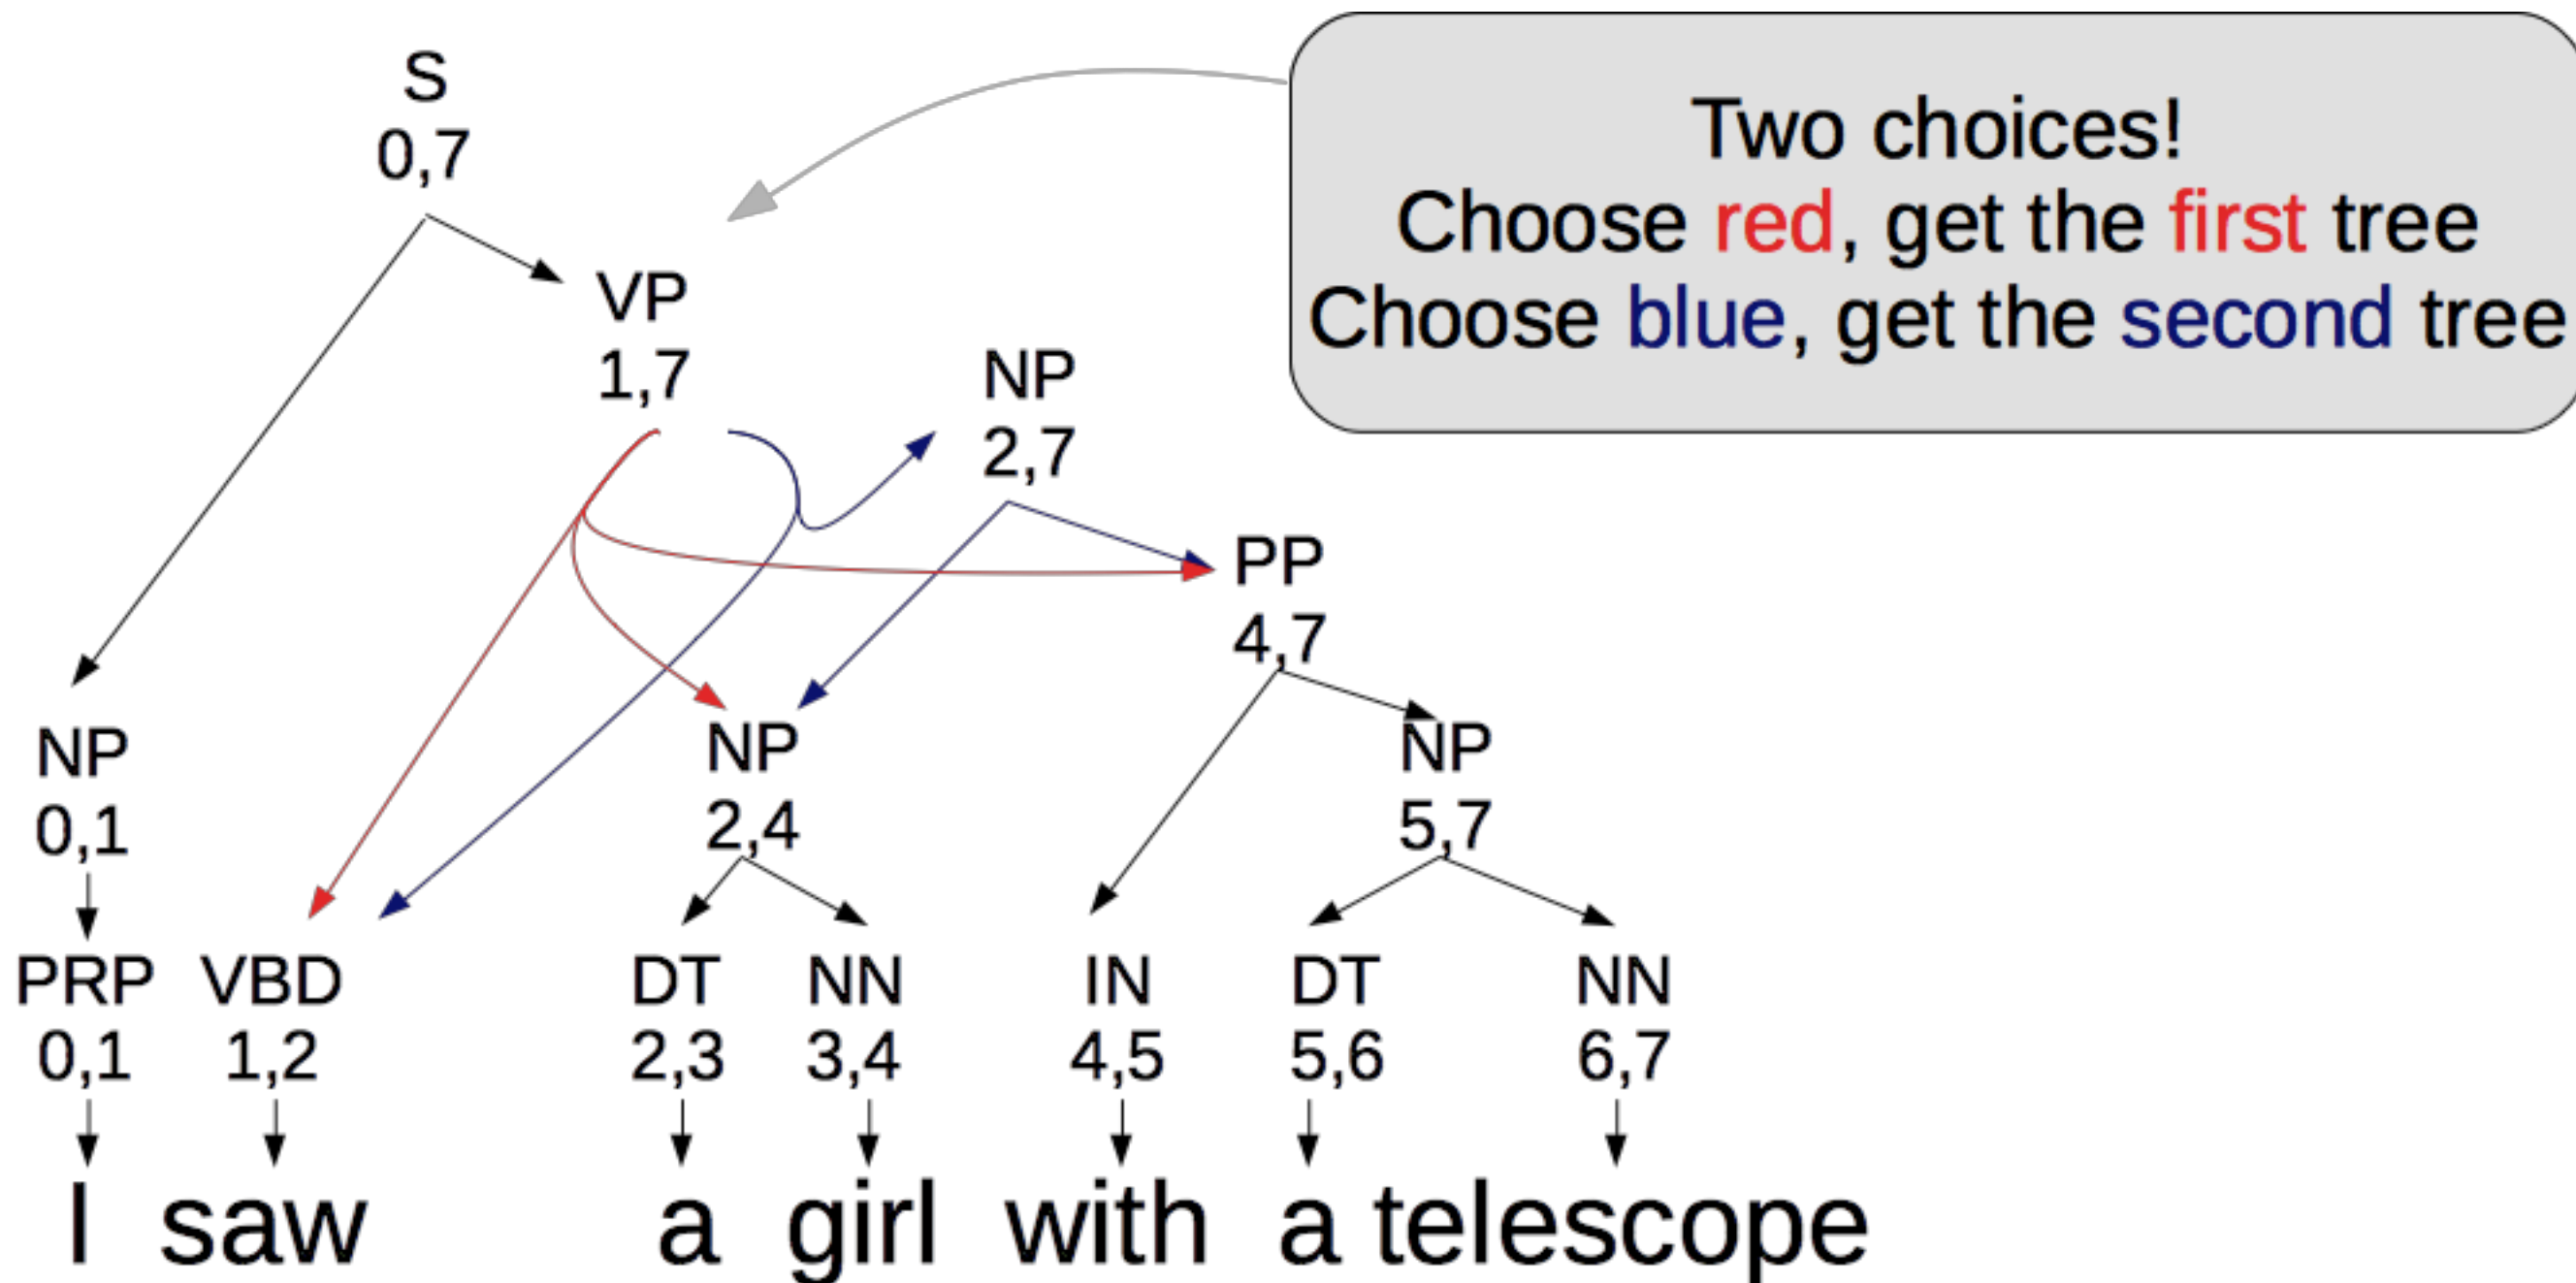

- The degree of a hypergraph is the maximum degree of its edges
- A graph is a hypergraph of degree 1!

Tree Candidates as Hypergraphs

- With edges in **one** tree or **another**

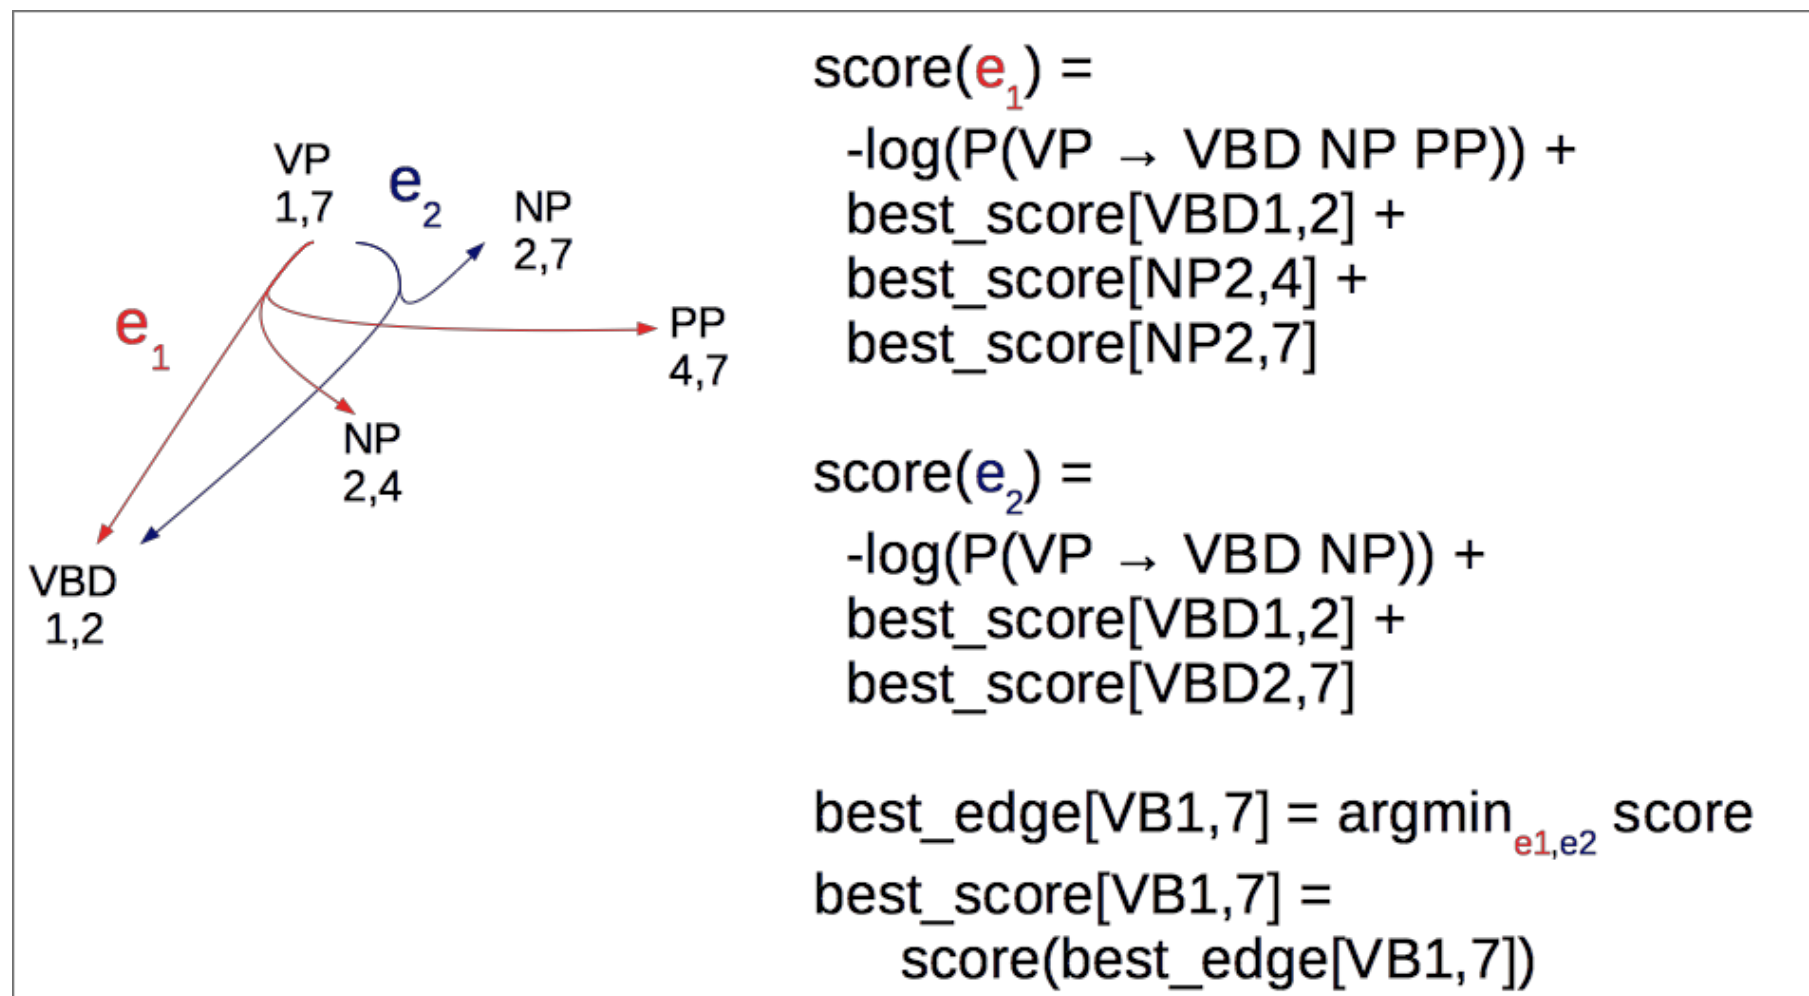

Weighted Hypergraphs

- Like graphs, can add weights to hypergraph edges
- Generally negative log probability of production

Hypergraph Search: CKY Algorithm

- Find the highest-scoring tree given a CFG grammar
- Create a hypergraph containing all candidates for a binarized grammar, do hypergraph search

- Analogous to Viterbi algorithm, but Viterbi is over graphs, CKY is over hyper-graphs

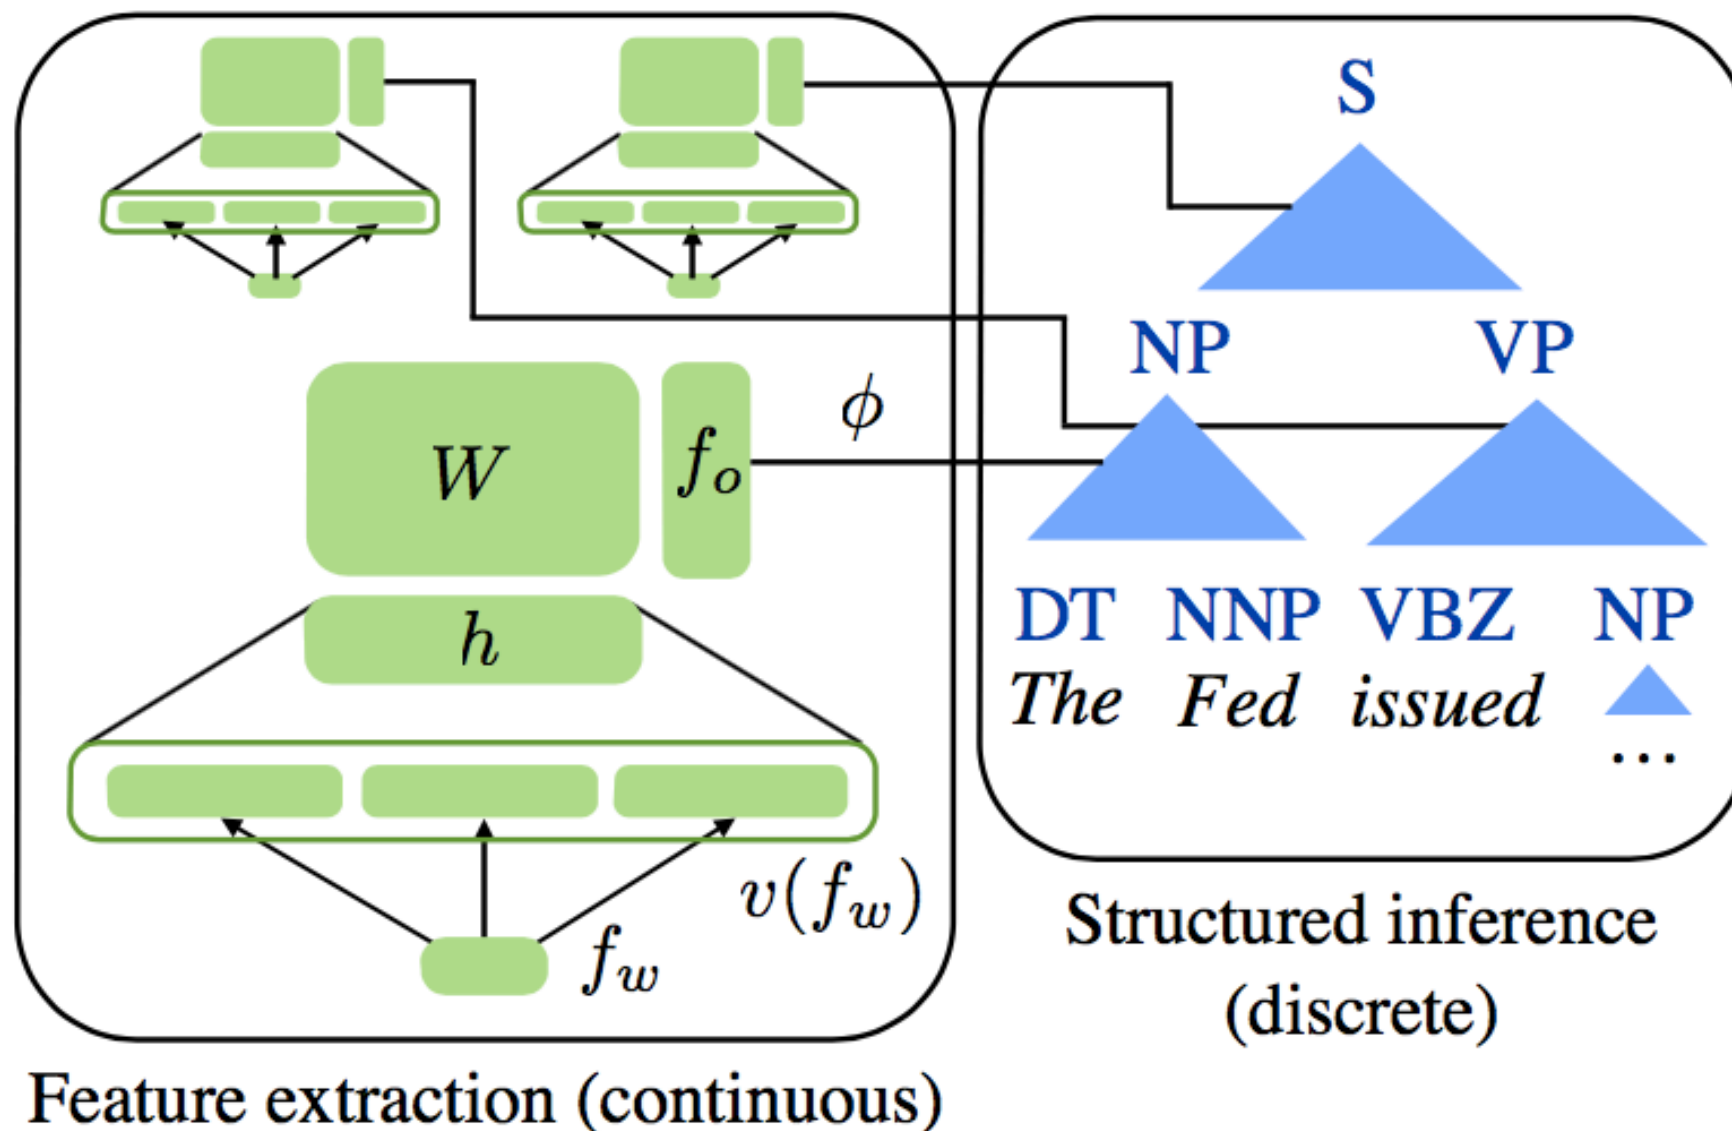

Hypergraph Partition Function: Inside-outside Algorithm

- Find the marginal probability of each span given a CFG grammar
- Partition function is probability of the top span
- Same as CKY, except we logsumexp instead of max
- Analogous to forward-backward algorithm, but forward-backward is over graphs, inside-outside is over hyper-graphs

Neural CRF Parsing

(Durrett and Klein 2015)

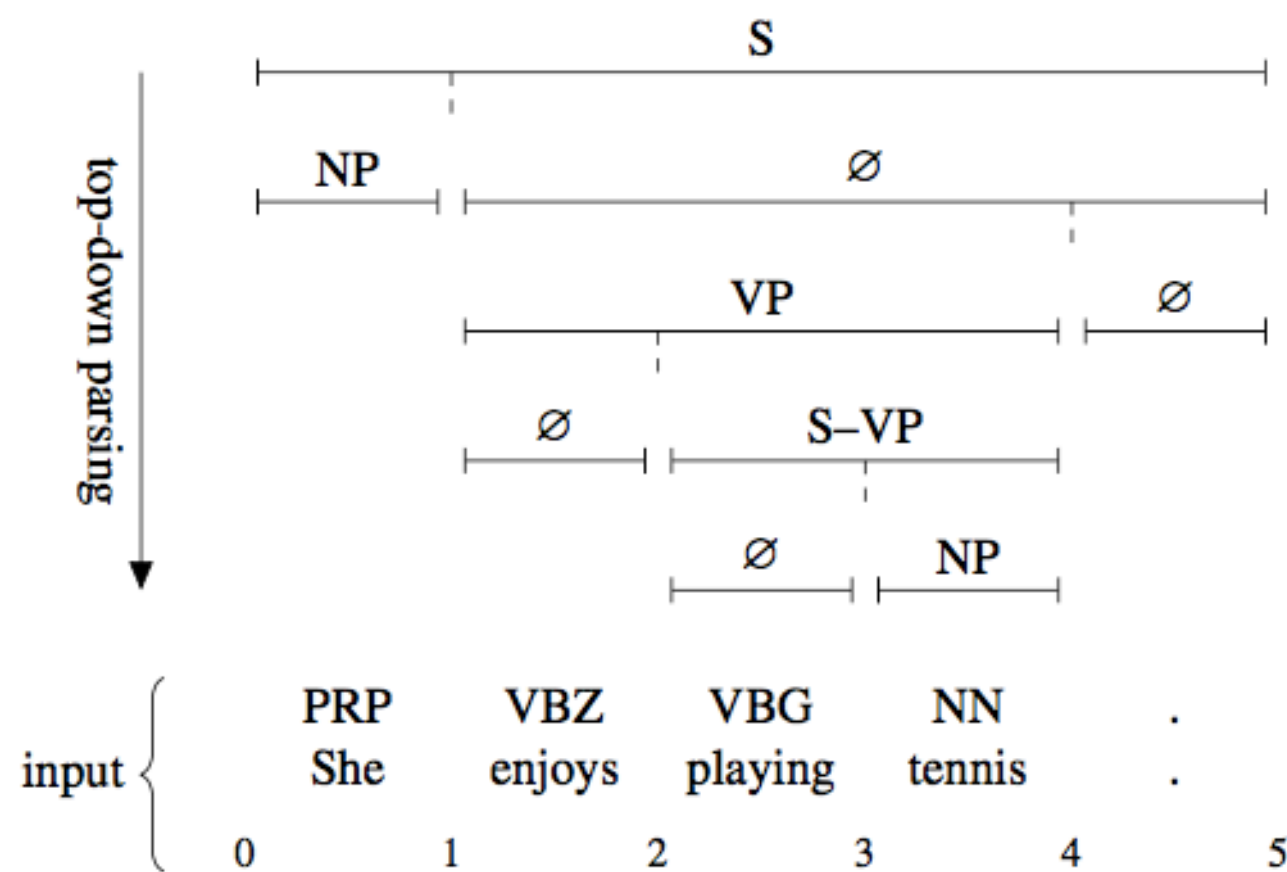

- Predict score of each span using FFNN
- Do discrete structured inference using CKY, inside-outside

Span Labeling

(Stern et al. 2017)

- Simple idea: try to decide whether span is constituent in tree or not

- Allows for various loss functions (local vs. structured), inference algorithms (CKY, top down)

An Alternative: Parse Reranking

An Alternative: Parse Reranking

- You have a nice model, but it's hard to implement a dynamic programming decoding algorithm
- Try reranking!
 - Generate with an easy-to-decode model
 - Rescore with your proposed model

Examples of Reranking

- Inside-outside recursive neural networks (Le and Zuidema 2014)
- Parsing as language modeling (Choe and Charniak 2016)
- Recurrent neural network grammars (Dyer et al. 2016)

A Word of Caution about Reranking! (Fried et al. 2017)

- Your reranking model got SOTA results, great!
- But, it might be an effect of model combination (which we know works very well)
 - The model generating the parses **prunes down the search space**
 - The reranking model chooses the best parse **only in that space!**

Candidates	Scoring models		
	RD	RG	RD + RG
RD	92.22	93.45	93.87
RG	90.24	89.55	90.53
RD \cup RG	92.22	92.78	93.92
